

Collaboration between EPROJETECH with the various International Postal Services has been achieved by providing RFID technology solutions. The main difficulty raised at the time of sorting and delivery of postal bags, was the impossibility to circulate in real time, the relative information regarding the transfer of the mail.

Pick-up and sorting times in almost every sorting office were too long and occurred various types of errors.

Postal services looked to resolve the problem by turning to RFID technology. Furthermore a system has also been created to verify quality of the service by inserting an UNDERCOVER BAG with another RFID chip inside the bag. The reader device can read numerous tags at the same time, in this way tracing their course. It is also possible, in the same way, to verify the transportation of the various sacks is carried out within the estimated delivery time.

The productivity gains are based on the fact that is possible to follow the postal bags in a automatic way during the whole logistical process until the delivery.
